prompt: "The San Andreas Fault" · mean confidence 0.31 · grey = prompt, blue = generated

The San Andreas Fault Zone, California, USA 5.3 Kinematic rupture model, slip distribution, and stress field. We identify the rupture scenario of the 1992 Landers, 1992 magnitude 7.9 earthquake: (1) We assume that a circular crack (moment tensor) is located on a pinch-out fault segment (e.g., Yagi and Yagada, 2005). The result of this study is similar to that of Topography Mapping and Reflection, but due to a lack of material from the MHT (e.g., Segall, 1996). However, we also find that the location of the hypocenter is in a region with a relatively low GMPE. Table 3 provides an overview of the results obtained. The results are consistent with the observations. These results are consistent with the studies reported in Yaman

why that token is light — next-token distribution at step 24: the model favored 'use' (p=0.09), but temperature sampling emitted 'identify' (p=0.00, orange)
